Text Supplement for ScholarWorks@UA collection

"Moment tensor catalog results for nuclear explosions, volcanic events,

and earthquakes"

Celso Alvizuri

Version 1: December 1, 2017

**Attribution:** If you use these files, please cite *Alvizuri et al.* (2017) and this ScholarWorks entry.

## Description of files

This collection is established for the submission of a manuscript (*Alvizuri et al.*, 2017).

Three catalogs of seismic moment tensors were generated using first-motion polarities, body waves, and surface waves. The best solution ($M_0$) was obtained through a grid-search in the moment tensor space using the 'cut-and-paste' (CAP) approach, which allows for different frequencies and time shifts on different portions of seismograms (*Zhao and Helmberger*, 1994; *Zhu and Helmberger*, 1996; *Zhu and Ben-Zion*, 2013). The moment tensor approach was adapted and applied in *Silwal and Tape* (2016) for double couple moment tensors and in *Alvizuri and Tape* (2016) for full moment tensors. A summary of figures in the collection is listed in the following table:

| figure | description | file name |
|--------|-------------|-----------|
| Figure A1 | Waveform fits for 32 events from the Nevada Test Site (NTS) (*Ford et al.*, 2009) | fmtu_llnl_nucs_fits.pdf<br>fmtu_llnl_quakes_fits.pdf<br>fmtu_llnl_coll_fits.pdf |
| Figure A2 | Waveform fits for 63 events from Uturuncu volcano (*Alvizuri and Tape*, 2016) | fmtu_uturuncu_fits.pdf |
| Figure A3 | Waveform fits for 21 events from southern Alaska (*Silwal and Tape*, 2016) | fmtu_alaska_fits.pdf |
| Figure B1 | Uncertainty plots for NTS events | fmtu_llnl_nucs.pdf<br>fmtu_llnl_quakes.pdf<br>fmtu_llnl_coll.pdf |
| Figure B2 | Uncertainty plots for Uturuncu events | fmtu_uturuncu.pdf |
| Figure B3 | Uncertainty plots for Alaska events | fmtu_alaska.pdf |
| Figure C1 | Time shift maps: one set of plots per event for NTS events | tshifts_spider_rayl.pdf<br>tshifts_spider_love.pdf |
| Figure D1 | Time shift plots: one plot per station for NTS events | tshifts_scatter.pdf |

Within the sets of figures, the 29 NTS events are in the same order as in *Ford et al.* (2009, Table 1), and the Uturuncu events and Alaska events are ordered by origin time.

**Figures A1, A2, A3: Waveform fits**

Waveform fits for 63 moment tensor inversions for which waveform misfit is plotted on the source-type plot. (Figure B). Black are observed waveforms; red are synthetic waveforms computed using a frequency-wavenumber method (*Zhu and Rivera*, 2002) that assumes a (1D) layered model. The waveforms are fit separately within five time windows: P wave vertical component (PV), P wave radial component (PR), Rayleigh wave vertical component (SurfV), Rayleigh wave horizontal component (SurfR), and Love wave transverse component (SurfT). At far left in each row is the station name, source-station distance in km, and station azimuth in degrees. Below each pair of waveforms are four numbers: the cross-correlation time shift between data and synthetics, the cross-correlation value, the percent of the misfit function represented by the waveform pair, and the amplitude ratio between waveforms, $\ln(A_{\mathrm{obs}}/A_{\mathrm{syn}})$, where $A$ is the max value of the waveform within the time window.

The beachball represents the best solution $M_0$ (i.e., the global minimum of the misfit function). The beachball is plotted as a lower-hemisphere projection (standard seismological convention) of the moment tensor. The surrounding black dots denote the azimuthal location of the stations used, and the red crosses denote the lower hemisphere piercing points of the ray paths to the stations.

Here is a header for an example event in Figure A1:

```
Event HOYA Model wes Depth 1
FM 263 51 6 Mw 4.70 gamma 0 delta 69 rms 5.531e01 VR 69.4 pol_wt 999.00
Filter periods (seconds): Body:0.103.33. Surf:6.6733.33 duration: 0.10/0.05 s
# norm L1 # Pwin 5 Swin 300 # N 21 Np 20 Ns 52
```

The four header lines are as follows:

1. `Event HOYA Model wes Depth 1`
   The event name is from Table 2 of *Alvizuri et al.* (2017). The layered model used is `wes`, and the event depth is 1 km.

2. `FM 263 51 6 Mw 4.70 gamma 0 delta 69 rms 5.531e01 VR 69.4 pol_wt 999.00`
   The orientation of the moment tensor solution $M_0$ is strike 263°, dip 51°, rake −6°. The estimated magnitude is $M_{\mathrm{w}}$ 4.7. The source type of $M_0$ is expressed in terms of lune longitude $\gamma = 0°$ and lune latitude $\delta = 69°$. The waveform difference between data and synthetics is $RMS = 0.5531$, and the variance reduction is $VR = 69.4\%$. These are based on a waveform difference measure that rewards using longer time windows and broader bandpass limits. This choice means that the $VR$ cannot be directly compared with $VR$ values reported in other studies.

   If polarities are use in the misfit function, then the factor `pol_wt` determines the balance between fitting waveforms and fitting polarities. A value of 999.0 means that polarities are not used.

3. `Filter periods (seconds): Body:0.103.33. Surf:6.6733.33 duration: 0.10/0.05 s`
   The body waves were filtered 0.10–0.33 s, the surface waves were filtered 6.66–33.33 s. The source time function is a trapezoidal function whose duration is 0.10 s and whose rise time is half the duration. The duration is not an estimated source parameter but is set according to the target frequency of body waveforms (here 10 Hz).

4. `# norm L1 # Pwin 5 Swin 300 # N 21 Np 20 Ns 52`

   An L1 norm was used for the misfit function (e.g., *Silwal and Tape*, 2016). The (reference) P-window is 5 s long and the surface wave window is 300 s long. There are 20 P wave windows (Np), 52 surface wave windows (Ns), and 21 stations (N).[1]

The numbers below each station are

1. source–station epicentral distance, km

2. station azimuth, in degrees

3. time shift between picked P onset and synthetic P onset.

4. sign of the observed first-motion polarity[2], which is either 1 (up or compression) or $-1$ (down or dilatation). The number in parentheses is the predicted amplitude, which ranges between $\pm\sqrt{2}$; numbers close to zero indicate that the station is near a nodal surface of the radiation pattern for the assumed mechanism.

The four numbers below each pair of waveforms are

1. the cross-correlation time shift $\Delta T = T_{\mathrm{obs}} - T_{\mathrm{syn}}$ required for matching the synthetics $s(t)$ with the data $u(t)$. A positive time-shift means that the synthetics arrive earlier than the data and that the assumed velocity model is faster than the actual earth structure.

2. the maximum cross-correlation percentage between $u(t)$ and $s(t - \Delta T)$

3. the percentage of the total misfit

4. the amplitude ratio $\ln(A_{\mathrm{obs}}/A_{\mathrm{syn}})$ in each time window

## Figures B1, B2, B3: Uncertainty plots

*Alvizuri et al.* (2017), Figure 4, caption:
Full moment tensor uncertainty summary for the HOYA nuclear explosion.
(a) Map of source location (red star) and stations used in the inversion for this event. xxx
(b) Contour plot of the polarity misfit on the lune, if polarities are used, as in the case of the Uturuncu events (*Alvizuri and Tape*, 2016). (c) Probability density for moment tensor source type, plotted in *vw* space (*Tape and Tape*, 2015). A green circle indicates the location of the maximum, which in general will differ from the source type of $M_0$. (d) Contour plot of the variance reduction $VR(\mathbf{\Lambda})$. The variance reduction $VR(\mathbf{\Lambda})$ at a point $\mathbf{\Lambda}$ is the maximum variance reduction $VR(M)$ for moment tensors $M$ that have source type $\mathbf{\Lambda}$ and that have correct polarities. Large values (blue) of $VR$ represent better fit between observed and synthetic waveforms. Of the beachballs $M(\mathbf{\Lambda})$, our desired solution $M_0$ (green box) is the one with largest $VR$; $M_0$ (and therefore its location on the lune) will change slightly based on the choice of a random grid search instead of the regular grid search used here, which is for plotting purposes. The gray arcs on

---

[1]For the case of the NTS events, the will generally be a discrepancy between the N in the header and the number of stations listed in Figure 3, which shows the unique number of stations used. Stations that are multiply listed for networks (e.g., TS.PFO and CI.PFO) or stations with different sensors for high-frequency and broadband recordings (e.g., LL.MNV.BB and LL.MNV.HF) would only get counted once in Figure 3 but multiple times for the N header.

[2]First-motion polarity measurements were only used for the events at Uturuncu volcano (*Alvizuri and Tape*, 2016).

the lune are the great circle arcs $\lambda_1 = 0$, $\lambda_2 = 0$, and $\lambda_3 = 0$. Selected eigenvalue triples (black dots) on the boundary of the lune are indicated, with the understanding that the triples need to be normalized. The positive isotropic source $(1, 1, 1)$ is at the top, the negative isotropic source $(-1, -1, -1)$ is at the bottom, and the double couple $(1, 0, -1)$, not shown, would be at the center of the lune. (e) The curves $\hat{V}'(\omega)$ and $\hat{P}'(\omega)$; they are used to construct the confidence curve $\mathscr{P}(V)$ in (f), as explained in *Silwal and Tape* (2016). For full moment tensors, the probability density of $\omega$ with respect to the homogeneous probability is $\hat{P}'(\omega) \propto \sin^4 \omega$. (f) The confidence curve $\mathscr{P}(V)$ for $M_0$. The more the curve resembles the shape of a capital gamma ($\Gamma$), the better. The shaded area is the average confidence $\mathscr{P}_{\mathrm{AV}}$. (g) The moment tensor $M_0$, plotted in a lower-hemisphere projection. The location of the piercing point for each station depends on the station azimuth, epicentral distance, and the assumed layered reference model.

### Figure C1: Time shift maps per event

For each event shown in Figure A1, we can collect the time shifts for Rayleigh waves and Love waves and plot them as "spider" plots. These plots are useful in assessing the possibility of cycle skipping between observed and synthetic waveforms. Since the time shifts are expected to be caused by differences between real Earth structure and the assumed 1D Earth structure, we expect the time shift patterns to be smoothly varying as the station azimuth changes. However, the time shifts can also be caused by errors in the assumed source hypocenter or origin time; hence we also examine the time shift plots per station (Figure D1).

### Figure D1: Time shift plots per station

For all the time shifts for Rayleigh waves and Love waves shown in Figure A1, we collect them by station to make the plots in Figure D1. These plots have the advantage over the time shift maps in Figure C1 in that the systematic influence of source errors will be reduced in Figure D1 (all sources, one station) vs Figure C1 (one source, all stations).

Note that different bandpasses were used for different events (Table 3); an alternative to showing the time shift would be to divide by the center of the bandpass and then plot the phase shift.

### Text file tables for moment tensor catalogs [`fmtu_XXXX_mech_extended.txt`]

Seismic moment tensor catalogs. Details can be found within the header lines, which also refer to *Kanamori* (1977); *Aki and Richards* (1980); *Silver and Jordan* (1982); *Minson et al.* (2007); *Tape and Tape* (2012, 2013, 2015).

### Input text files used in the moment tensor inversion [`fmtu_weights_XXXX.zip`]

We provide a text file for each of the 63 events in this study. These files show which stations and which time windows were used (or not) in each moment tensor inversion. It also shows the first-motion polarity observations that were used.
